2Department of Soil Quality, University of Wageningen, Netherlands.

Authors’ contributions

This work was carried out in collaboration between both authors. Author ANO designed the study, performed the mycological analysis and wrote the protocol and the first draft of the manuscript. Author TWK managed the analyses of the study, the literature searches. Both authors read and approved the final manuscript.

ABSTRACT

For millennia, wild edible mushrooms (WEM) had always been considered as substantial food and medicinal sources, for local communities, both Bantu and indigenous peoples. However, few information and sparse data are available on useful mushrooms of Cameroon. A study was undertaken to update the checklist of WEM in humid forests of Cameroon. From mushroom excursions, surveys and inventories, thousand fungal specimens were collected in situ, described and identified using key features and references. Wild edible mushrooms were recruited in three trophic groups. They denoted a dissimilar national biogeographical distribution. Saprophytes and Termitomyces were encountered throughout the country; ectomycorrhizal mushrooms occurred in forest clumps, only in three regions: South, Southeast and Southwest. 117 WEM were listed belonging to 17 families and 43 genera, including nearly 22 Termitomyces, 32 ectomycorrhizal and 63 saprophyte species. 15 WEM were also
claimed to have medicinal properties. This vast mushroom diversity related to various specific habitats and ecological niches. Five fungal groups were considered as excellent edible. *Amanita* and *Boletus* species were seldom consumed. Most mushroom species were harvested solely for home consumption, with the exception of *Termitomyces*, the only marketed mushroom. In fine, the diversity of WEM was high but poorly known and valorized. To fulfill the Nagoya convention, it is recommended to pursue mycological inventory of macrofungi in Cameroon, including the use of molecular tools and to cultivate local wild edible saprophyte mushrooms.

**Keywords:** Amanita; boletus; chanterelles; ectomycorrhizae; saprophytes; *Suillus* granulates; *Termitomyces.*

1. **INTRODUCTION**

For millennia, sedentary Bantu and indigenous people of humid forests called Baka in East and Bagyeli in South Cameroon have been eating wild edible mushrooms (WEM), to supplement and diversify their diet [1,2]. In this context, consumption and utilization of wild mushrooms constitute long-term traditional and cultural practices. However, communities of wild edible mushrooms (WEM) of Cameroon that represents an important food biodiversity source remain poorly known and valorized.

In sub-Saharan Africa, about 2500 species of wild edible macrofungi have been identified [3]. A first literature review published usages and relevance of edible mushrooms on diet of local populations of sub-Saharan Africa [4]. Several studies reported the abundance of mushroom in Burundi, Ghana and Tanzania [1,5,6,7,8]. Mushroom significance and usage had been described for the Yoruba community in Nigeria and the pygmys of Central African Republic [9, 10,11]. Data exist on the nutritive value of mushroom species of the Miombo dry forest [12,13]. Knowledge and utilization of edible mushrooms by Bantu and Bagyeli populations in the rainforests of South Cameroon have been recorded along seasons of the year [14]. The nutritive and the medicinal effect of WEM are thus well-known in sub-Saharan Africa since time immemorial. WEM are rich in vitamins (almost the entire B complex, folic acid, ergosterine (provitamin D), thiamin, riboflavin), in minerals such as potassium, phosphorus, cupper, sodium, iron, manganese and calcium, in digestive fibers (mannoses, polysaccharides, cellulose, chitin fibers), and in proteins of value higher than most legumes [15,16].

Wild edible mushrooms are also economically important. For example, in most developed countries, mushroom cultivation of *Agaricus bisporus* (J. F. Lange) Imbach, *A. campestris* (L.) and *Lentinus edodes* (Berk.) Pegler, in North America, Europe and Asia is an important revenue source [16]. In these countries, they are as well picked up in autumn by amateur and professional mycologists for selling in large supermarkets and restaurants, thus constituting an old multibillionaire industry in American dollars. In Burundi, women claim rights on portions of land were *Termitomyces* begin to fruit [1]. In Cameroon, old women attentively watch over termite mounds on the vicinity of their land and forbid anyone to carry away even a piece of mud from it, to protect *Termitomyces* mushroom. Moreover, a particular group of edible mushrooms, symbiotic with roots of some endemic timber species of humid forests (*Gilbertiodendron, Microberlinia, Tetraberlinia, Uapaca...*) have an international worthy market, thus offering an opportunity to develop a mushroom export value chain as well as insuring forest protection and environmental education. Many WEM are used in traditional pharmacopeia in Africa and Asia, to cure blood pressure, tumors and viruses. The edible species *Tremella fuciformis* (Berk.) (locally called “Biyae” in Bulu) and *Tricholoma matsutake* (CV. Head) Sacc (Called Shi’itake in Chinese) cure leukemia in 65% of patients; polysaccharides of *Lentinula edodes* species constitute an immunological stimulant used to cure viral hepatitis and to protect the liver; species of *Ganoderma lucidum* (Curtis ex Fr.) *P. karst* and *T. fuciformis*, have anti diabetes and anti oxidant effects [8,16].

For Cameroon, the first discoveries of wild edible mushrooms can be traced back up to the 19th century [9,17,18,19]. The first four recognized wild edible species were *Leptota discipes* (Heim), *Marasmius* spp; *Mycena* spp and *Lactarius gymnocarpus* (Heim ex Singer) in Ebolowa, South Cameroon. Since then, numerous inventories have been carried out on wild edible macrofungi with or without medicinal effect. These studies had approximately two major periods, from colonial era to the end of the 20th century, and from the first 10 years of the third millennium till nowadays. The objective of
this study was to update the checklist of WEM of humid forests in Cameroon, in the bid to contribute to help Cameroon complying with the Nagoya Convention on biodiversity.

2. MATERIALS AND METHODS

2.1 Study Sites

Numerous mycological and ethnomycological studies have been carried out on wild edible mushrooms in humid forests of South Cameroon. It is a vast area, below parallel 7th south, with scattered savanna enclaves, small food farms, fallows of Chromoleana odorata (L.) R.M.King & H.Rob., and Imperata cylindrica (L.) P.Beauv., small cocoa farms, secondary forests at different stages of forest regeneration, skid trails and wood lot parks. It covers six administrative regions, namely, Centre, East, Littoral, North-west, South and South-west (Fig. 1).

Fig. 1. Map of localization sites of mushroom excursions in Grand-South Cameroon (Yellow circles)
Mushroom excursions and inventories were conducted in portions of the dense evergreen humid forests [20], including Mount Cameroon mountain forests, Northwest rocky forests (near Fundong), Southwest lowland rainforest, lowland humid forest of the Bipindi-Lolodorf-Akom II triangle, the forest-savanna transition area, along the Obala-Batchenga road, lowland secondary forest of the Centre zone, lowland savannas of the Mbam, highland savannas of Western Highland Plateau, and lowland Southeast rainforests, near Ngoïla (Fig. 1).

Nearly 40 localities were covered, namely, Abong-Mbang, Abu, Bafia, Bafoussam, Bantoum, Begni, Bipindi, Bintom, Bitchoka, Bityili, Bokito, Buea, Diba, Doumé, Ebebda, Ebimimbang, Ebom, Ebolowa, Foumban, Fundong, Gribé, Kedia, Koutaba, Lambi, Lobo, Lolodorf, Lomie, Ngat, Ngola, Ngoyang, Ngoumou, Nkongabok, Nkongzok, Ntui, Nyangong, Obala, Okola, Tchékos, Tobagne, Touké, Zoka, Zoulabot.

Climate is hot and humid, with ample rainfalls, varying with altitude and latitude. Relative humidity is generally above 80%, year round [21]. Geologically, the area varies from Precambrian metamorphic rocks to recent volcanic intrusions [22]. Physico-chemical soil features as well vary from Andosols rich in P to Ferralsols, poor in N, P, and K.

### 2.2 Ethnic Groups

During field works, several ethnic groups were encountered, notably, Bantu people of Bakweri, Bakossi, Bamoun, Bamileké, Bassa, Bulu, Ewondo, Eton, Fang, Kom, Konabembe, Makakozimé, Manguissa, Ngumba, Osananga, Yambassa, and two indigenous (often called pygmies) Bagyeli Baka people, living mainly in forest settlements. While the Bantu people live on shift and ing cultivation and collection of Non timber forest products (NTFP) like wild fruits and WEM, during harsh periods, the indigenous live people live on gathering and hunting NTFP (mostly WEM) as their main subsistence activities.

### 2.3 Ethnomycology Survey

Since 1996 to 2015, surveys were undertaken in numerous villages and forest settlements, with the aid of field assistants. They were selected and trained to assist in conducting ethnomycologycal surveys and to serve as field guides. The survey to assess local perceptions
and endogenous knowledge on WEM began with a display of a compendium of identified local WEM. Thereafter, a questionnaire was used to obtain information from a representative group of men, women and youth, as well as traders in nearby markets with experience on local WEM trading.

2.4 Mushroom Collection, Description and Preservation

Mushroom excursions took place during both rainy seasons (March-June and August-November). Various collecting grounds used by local populations and forest clumps were covered, including undisturbed forest, secondary forests, cocoa plantations, food crop fields, bush fallow, farmers’ trails and home gardens. Sometimes, some people spontaneously brought collected specimens for identification during the period the research team spent in a village.

Collected specimens were macroscopically described, photographed in fresh state under daylight, dried for 2-3 days at around 40°C, in locally made plywood drier. Some specimens were kept fresh in 50% alcohol in a local herbarium. Macroscopic characters described were: the habitus and growth patterns, cap shape and texture, stipe shape, texture, flesh and length, universal and partial veils if present, hymenophora and latex. After drying, microscopic characters of exsiccates were observed under microscope by observing spore morphology and volume, spore dimensions, ornamentations, trama and hymenium, basidium and ascum, cystidia, pileus surface, stipe surface, volva dimensions and clamp connections. A database of identified WEM was set up and partial description keys developed for each trophic fungal group using generic characters and specific features, successfully numbered, in cascades.

3. RESULTS

3.1 Diverse Habitats

Three trophic groups of wild edible mushrooms were found, with saprophytes and Termitomyces occurring all over the country. Symbiotic-tree mushrooms (ectomycorrhizal mushrooms) were found only in the South, East and South-west regions. Ectomycorrhizal mushrooms were exclusively associated with various “Ekop”1.

Uapaca tree species, Gilbertiodendron spp and Microberlina bisulcata A.Chev., respectively. In these spots, they formed small to large forest clumps, sometimes as large as 20 km long stretch X 1-3 km depth, like on the road Lomie to Ngoïla, after crossing the Dja river, in the South-east region.

3.2 Dissimilar Biogeography

Three trophic groups of wild edible mushrooms were found, with saprophytes and Termitomyces occurring all over the country. Symbiotic-tree mushrooms (ectomycorrhizal mushrooms) were found only in the South, East and South-west regions. Ectomycorrhizal mushrooms were exclusively associated with various “Ekop”2. Uapaca tree species, Gilbertiodendron spp and Microberlina bisulcata A.Chev., respectively. In these spots, they formed small to large forest clumps, sometimes as large as 20 km long stretch X 1-3 km depth, like on the road Lomie to Ngoïla, after crossing the Dja river, in the South-east region.

3.3 Vast Abundance and Diversity

One hundred and seventen species of wild edible mushrooms were listed from Cameroon humid forests, belonging to 17 families and 43 genera, including 63 saprophyte, 32 ectomycorrhizal mushroom and Termitomyces 22 species (Table 1).

Five groups of wild edible mushrooms were considered excellent edibles, including Armillaria katangensis, the 15 Cantharellus and Termitomyces species, and Volvariella volvacea (Bull) Singer. Good edibles were some species of eight genera Cookeina, Flammulina, Lentinus, Macrolepiota, Marasmius, Psathyrella, Pleurotus, and Tremella. Less collected mushrooms included species of 13 genera: Collybia, Daldinia, Gymnopilus, Mycena, Pluteus, Polyopus, Ramaria, Russula, Sarcosoma, Schizophyllum, Sparassis, Stereum, and Trametes. Mushroom species rarely or never collected were genera of Amanita, Boletus, Craterellus, Gomphus, Lactifluus, Phlebopus, Russula, Suillus, and Strobilomyces species (Table 1).

---

1 The word “Ekop” referred to a group of unnamed Caesalp tree species by forest prospectors (Mouranche and Letouzey 1952).

2 The word “Ekop” referred to a group of unnamed Caesalp tree species by forest prospectors (Mouranche and Letouzey 1952).
In general, collected mushrooms were cooked and eaten. Only *Termitomyces* species in year of abundance were sold, fresh or dried, along roadsides and in urban markets. No WEM of abundance were sold, fresh or dried, along and eaten. Only  

Fifteen species of wild edible mushrooms were also collected for their medicinal properties, including the following genera: *Agaricus, Auricularia, Cookeina, Cyathus, Daldinia, Flavolus, Ganoderma, Pleurotus, Tremella, Termitomyces* and *Russula*.

Only one mushroom species was recognized by populations of the Mount Cameroon area, *Chlorophyllum molybdites* (G. Mey.) Massee, as provoking hallucinations and, sometimes used for mystic incantations by traditional healers (Table 2).

4. DISCUSSION

More than one hundred species of wild edible mushrooms, belonging to three trophic groups, were recorded from humid forests of Cameroon. This vast diversity included 58% saprophyte, 28% ectomycorrhizal and 14% *Termitomyces* species. It is the first time that such a high biodiversity in WEM is reported from Cameroon. Our results largely contradict FAO reports [2,23, 24,25]. In fact, inventory reports on wild edible mushrooms of Central Africa seem largely inaccurate and deserve to be rapidly updated, with regard to rapid deforestation and genetic erosion of biodiversity in this region. Rural populations of Baleng, near Bafoussam in West Cameroon, seemingly collected a specimen of *Termitomyces titanicus* (Pegler & Piearce), in the mid-1990s. Ten years later when we visited the locality, they claimed not to have seen it again. One of the authors did observe similar trends with the exotic ectomycorrhizal edible mushroom, *Suillus granulates* (L.) Roussel, occurring on pine roots, in Yaoundé and Dschang (Onguene, pers.obs, 2014). Such observations related to the disappearance of wild edible mushrooms were also made in Burkina Faso [26]. This phenomenon of mushroom disappearance may suggest early events due to global warming for Cameroon humid forests.

This mushroom inventory was far from complete because it did not include wild edible mushrooms of the Adamawa and North regions neither exhaustive in several localities. Quite a few
Photo 1. Wild edible mushrooms of humid forest of Cameroon by trophic group from top to bottom: Saprophytes, Termitomyces and Ectomycorrhizae

Wild edible mushrooms of humid forest of Cameroon by trophic group from top to bottom: Saprophytes, Termitomyces and Ectomycorrhizae
collected mushrooms could not be identified to species level. Indeed, our results are limited by lack of a national inventory on wild edible mushrooms of Cameroon, using molecular tools. Therefore, the biodiversity of WEM in Central Africa largely remains ill-known [27,28].

Cameroonian mycological cuisine differed from that of Europeans and Asians. While the latter eat more ectomycorrhizal mushrooms, Cameroon forest-dwellers feed on a mixture of saprophytes, *Termitomyces* and only, two groups of ectomycorrhizal mushrooms. Strikingly, they seldom collected for consumption *Amanita*, *Boletus* and most ectomycorrhizal mushrooms. Cameroonian WEM basket is nearly similar to that of several sub-Saharan countries such as Burundi, Gabon, Nigeria, DR Congo and Rwanda [2,29,30]. Cameroon forest-dwellers feed on three trophic mushroom groups, thus allowing diet complementation and diversification for local populations, year round and, full harnessing of ecosystem continuum in various habitats. Hence, mushrooms’ exploitation fosters local populations’ strategy for sustainable natural resource management.

The major interest in mushrooms lies in their matchless flavor. It is the essential reason for their success for gourmets and gastronomes. But their palatability is differently appreciated. Four criteria can be used to evaluate mushroom’s palatability: Consistency, aroma, taste and aspect [1,31]. Excellent mushrooms have the four qualities. When one of these qualities is missing, the mushroom is qualified as suitable for eating. Those with two qualities are ordinary mushrooms and those with only one quality are hardly edible. In humid forest of Cameroon, five mushroom groups from local populations’ perceptions are considered as excellent comestibles, notably, the 15 *Cantharellus* and all *Termitomyces* species, the straw mushroom, *Volvaria* volvacea and the saprophyte *A.katangensis*. Our results differ from those of earlier research conducted in Central African Republic [32]. Several saprophytic species were considered as good comestibles like saprophyte species of the following seven genera *Auricularia*, *Cookieina*, *Leptiotus*, *Lentinus*, *Marasmius*, *Pleurotus*, and *Tremella*. Ordinary edible mushroom species included the majority of species (Table 1). One species, *Favolus brasilensis* (Fr.) Fr., the Brazilian polypore, locally called "Ongo", with a slim and tough flesh, not modified upon cooking, was mostly used as a potage during wet evenings. In general, *Amanita*, *Boletus* species and most ectomycorrhizal mushrooms are seldom collected for consumption by local populations. Indigenous pygmy people considered that changing color of Boletes after bruising or exposure to air is an obvious sign for their strong toxicity. Such a remark was also claimed in Tanzania [33]. Toxicity of local mushrooms has been a quest throughout our inventories. During three years of intensive mushroom excursion in the same plots, both authors did not record toxic or poisonous mushroom (Onguene & Kuyper, pers.obs. 2010). Only *C.molybdites* was strongly claimed as a poisonous mushroom by local Bakweri people in the Mount Cameroon region. In the same area, *C. molybdites* was also considered to provoke some deteriorations and hallucinations, or even used for mystic practices by traditional healers [24]. When kept in 50% alcohol, this whitish large mushroom became murky and the solution totally dark.

The habitats and ecological niches of wild edible mushrooms highly varied. For example, the straw mushroom grows only on decomposing palm oil trunk; the unique habitat of *Pleurotus tuber-regium* (Fr.) Fr is its grayish sclerotium; *A. katangensis* is readily identified in the field as an under-wood mushroom growing on a whitish velvety mycelia carpet; chanterelles and *lactarius* species grow symbiotically on roots of Ceasalps or *Uapaca’s* roots only in specific forest clumps, in rain forests of South, Southeast and Southwest regions [27,34,35,36]. Other edible ectomycorrhizal mushrooms not eaten by local populations of Cameroon were also collected and described from forest clumps, independently of soil types and climatic conditions. This attests the strong ecological specificity of ectomycorrhizal edible mushrooms with endemic tree species: no mushrooms, no trees. This simple ecological principle should serve for environmental education in Central Africa in order to boost humid forest conservation and environmental education. Such a pre-emptive action is required since there is no sound technical approach available for artificial regeneration of endemic ectomycorrhizal timber species of tropical humid forests.

Edible ectomycorrhizal mushrooms are potentially high in number in Cameroonian humid forests, largely unknown, though. In this case, 15 *Cantharellus* species are highly appreciated. Local Bantu and Pygmy people systematically eat all chanterelles and give them several local names (in "Bulu Cameroonian language")
according to substrate, habitat and taste, namely “Bingobindong, Otsetsa, Otoe, Mebem, Otoye mebem”. In a systematic plot sampling for three years, more than 1000 ectomycorrhizal fungal species were collected and nearly 200 species identified from ectomycorrhizal forest clumps. However, most of them are not collected and eaten by local people like species of the following genera Afroboletus, Amanita, Boletus, Craterellus, Lactarius, Lactifluus, Russula, Tuboseata... consumed elsewhere in Africa, Europe and Asia, though [2,27,36]. In the context of preventing food insecurity in the midst of poverty, these symbiotic mushrooms could serve as an alternative food source for local populations. In addition, wild edible ectomycorrhizal mushrooms could spur a new value chain in exports of WEM from humid forests of Cameroon, thus providing additional income to poor rural farmers. One kilogram of Chanterelle is worth slightly 19 650 CFA francs (30€) in Europe. Hence, a new wild edible mushroom value chain has potential to contribute to forest preservation and ecotourism.

Termite-mutually associated mushrooms, Termotomycos, are highly valued by local populations. All Termotomycos species are systematically collected and eaten after cooking. Across the country, these species depicted a particular size distribution along ecosystems. Small size Termotomycos species prevailed in forest ecosystem while middle size Termotomycos species abounded in grass savannas of Highland Plateaus of West Cameroon [37]. The large sized Termotomycos schimperi (Pat.) R. Heim species showed a strong zonal specificity. They occurred only in the forest-savanna transition road, between the cities of Obala and Ebebda (Fig. 1). T. schimperi, have been largely observed in sub-Saharan Africa, notably in Benin, Burkina Faso, Gabon, Mozambique, Central African Republic, DR Congo, Senegal, The Gambia, Zambia and Zimbabwe [29,38,39,40,41] In Cameroon it has been observed so far only in a very restricted area, the forest–savanna transition zone, along the Obala-Ebebda road. Confining of T. schemperi was also observed in the Kerala state in West India [42]. The symbiosis of fungus-growing termites and their associated mutualistic fungi, Termotomycos, has a single African origin and secondary domestication of other fungi or reversal of mutualistic fungi to a free-living state has not occurred, thus leading to co-evolution or co-cladogenesis [43,44,45,46]. Thus, T. schemperi together with its associated termite, Termes bellicosus, or Macrotermes michaelsen [47] developed a strong local ecological niche, likely related to particular rainfall patterns.

Wild edible mushrooms collected are readily eaten after cooking owing to their unpredictability in time and nature. However, Termotomycos species are harvested, dried and sold by women and children along road sides and in urban markets. In urban markets of Yaoundé, one specimen of T. schemperi is sold fresh 100 – 200 CFA francs (Onguene, Obs. pers., 2014). Hence, the local market of WEM is dominated by Termotomycos species. Yet, supermarkets, restaurants and hotels seldom sell local WEM. Termotomycos species are also sold fresh on road sides and dried in markets in other cities in sub-Saharan Africa [1,41].

The majority of wild edible and medicinal mushrooms are saprophytes. They belong to 31 genera and 63 species, all potentially amenable to cultivation. Accounting for the high agricultural potential of Cameroon, this plethora of wild edible saprophytes implies a huge potential in valorization of the numerous agricultural wastes, such as maize cobs, rice straw, cotton crabs, sugar cane trashes or coffee kernels. Therefore, edible saprophyte species could have immediate effects on job creation, trading and increasing agricultural revenues to rural women and young unemployed people [48]. In Vietnam, the straw mushroom is integrated to rice production [40]. But, there is still a large deficiency in mushroom spawn, thus limiting cultivation of wild saprophyte mushrooms and valorization of agricultural wastes in Cameroon.

Some species of wild edible mushrooms can have medicinal properties. In this study, 15 such species were recorded as having medicinal virtues. In general, this function always was considered secondary and information detained only by few interviewers. In tropical Africa, usages and practices of WEM in traditional pharmacopeia involve cosmetics, dyes, fumigation of traditional attic, and to tie jewelry [4,15]. For Bantu people, P. tuber-regium sclerotium could improve lactation in breast feeding women and heals heart palpitations. In East Cameroon, these sclerotia are collected in the forest, and sold by Konamembe Bantu and Baka pygmies to Nigerian traders who export them in Nigeria for trading to traditional healers. In Nigeria and Madagascar, P. tuber-regium sclerotium is used as anti poisonous remedy, to make charms for young ladies and to heal chest
pains. In Burundi, termite nests are used to heal heart attack [15]. Cookeina sulipes (Berk.) Kuntze, C. tricholoma (Mont.) Kuntze and Termitomyces lignilosius can also heal ear inflammation and mumps. Other WEM also relieve numerous pains and aches but information was not released. Our results are consistent with earlier workers [9,10,38,24]. In Benin, Nigeria and Madagascar, several species indicated in Cameroon seemed to prevent or even heal many diseases such as ear inflammation, mumps, rheumatism, women infertility, even cancers [16].

5. CONCLUSION

In fine, diversity and abundance of useful mushrooms in humid forests of Cameroon are high, yet poorly known and weakly valorized. To fulfill the Nagoya convention signed by Cameroon, it is recommended to pursue mycological inventory of macrofungi of Cameroon, including the use of molecular tools and, to harness local wild edible saprophyte mushrooms on-farm cultivation activities.

ACKNOWLEDGEMENTS

Acknowledgments to the Institute of Agricultural Research for Development (IRAD) and The Netherland Organization for the Advancement of Science (NWO) for financial support, Dr Ngome Ajebeson and Ingenieur Awana Patrick Stephane for English editing of one version of the manuscript as well to anonymous reviewers.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
